Abstract

*Burkholderia ubonensis* is an environmental bacterium belonging to the *Burkholderia cepacia* complex (Bcc), a group of genetically related organisms that are associated with opportunistic but generally nonfatal infections in healthy individuals. In contrast, the near-neighbour species *Burkholderia pseudomallei* causes melioidosis, a disease that can be fatal in up to 95% of cases if left untreated. *B. ubonensis* is frequently misidentified as *B. pseudomallei* from soil samples using selective culturing on Ashdown’s medium, reflecting both the shared environmental niche and morphological similarities of these species. Additionally, *B. ubonensis* shows potential as an important biocontrol agent in *B. pseudomallei*-endemic regions as certain strains possess antagonistic properties towards *B. pseudomallei*. Current methods for characterising *B. ubonensis* are laborious, time-consuming and costly, and as such this bacterium remains poorly studied. The aim of our study was to develop a rapid and inexpensive real-time PCR-based assay specific for *B. ubonensis*. We demonstrate that a novel *B. ubonensis*-specific assay, Bu550, accurately differentiates *B. ubonensis* from *B. pseudomallei* and other species that grow on selective Ashdown’s agar. We anticipate that Bu550 will catalyse research on *B. ubonensis* by enabling rapid identification of this organism from Ashdown’s-positive colonies that are not *B. pseudomallei*.

Introduction

The Gram-negative *Burkholderia* spp. comprise an ecologically diverse group containing over 70 species [http://www.bacterio.ict.fr/b/burkholderia.html], some of which are pathogenic to humans, animals or plants [1,2]. *Burkholderia pseudomallei* is the best-known member of the genus due to its ability to cause the potentially fatal disease melioidosis [3] and its bioterror potential [4]. *B. pseudomallei* was recently added as a Tier 1 Select Agent in non-endemic regions as the organism can cause melioidosis, a disease that can be fatal in up to 95% of cases if left untreated. *B. ubonensis* is frequently misidentified as *B. pseudomallei* from soil samples using selective culturing on Ashdown’s medium, reflecting both the shared environmental niche and morphological similarities of these species. Additionally, *B. ubonensis* shows potential as an important biocontrol agent in *B. pseudomallei*-endemic regions as certain strains possess antagonistic properties towards *B. pseudomallei*. Current methods for characterising *B. ubonensis* are laborious, time-consuming and costly, and as such this bacterium remains poorly studied. The aim of our study was to develop a rapid and inexpensive real-time PCR-based assay specific for *B. ubonensis*. We demonstrate that a novel *B. ubonensis*-specific assay, Bu550, accurately differentiates *B. ubonensis* from *B. pseudomallei* and other species that grow on selective Ashdown’s agar. We anticipate that Bu550 will catalyse research on *B. ubonensis* by enabling rapid identification of this organism from Ashdown’s-positive colonies that are not *B. pseudomallei*.

Misidentification of *Burkholderia* spp. has implications for environmental studies, clinical diagnosis and biosecurity responses [8], especially for *B. pseudomallei*, where false-negative and false-positive results may have serious consequences. Species misidentification can have an economic impact, as demonstrated by false-positive calls of near-neighbour species under the BioWatch program, which was introduced in the United States in 2003 to monitor aerosol samples for the presence of Select Agent organisms in the environment [9]. Detecting *B. pseudomallei* from clinical samples is also a nontrivial endeavour. Most hospital laboratories use standard culture media (e.g. MacConkey, horse blood and chocolate agars) for culturing of clinical specimens. Morphological identification of *B. pseudomallei* in contrast presents unique challenges. In endemic regions, *B. pseudomallei* is typically enriched from environmental specimens using broth selection [12].
followed by plating on Ashdown’s agar (ASA) [13]. However, no selective method is B. pseudomallei-specific. Indeed, many Burkholderia spp. residing in the same niches as B. pseudomallei, including B. ubonensis, are morphologically similar on ASA [10,14,15].

Since the “Burkholderia uboniae” species was first proposed in 2000 [16], little research has been conducted on B. ubonensis, despite being a potentially important biocontrol agent for B. pseudomallei [15]. Dideoxy sequencing-based genotyping approaches such as multilocus sequence typing (MLST), recA and 16S sequencing have been developed for Burkholderia spp. characterisation [9,17,18]. However, there are currently no cost-effective, rapid, and simple methods for detecting and differentiating B. ubonensis from other Burkholderia spp. including B. pseudomallei. For example, the type III secretion system 1 (TTS1) assay [19] only detects B. pseudomallei, and thus cannot further identify other species that grow on ASA. Therefore, the major aim of our study was to differentiate B. ubonensis from B. pseudomallei, with a secondary aim of differentiating B. ubonensis from other members of the Bcc and non-Burkholderiaceae organisms that also grow on ASA.

Materials and Methods

Ethics Statement

The Australian isolates used in our study were obtained from either private land or from Aboriginal communities. Prior to private land soil and water sampling, we obtained signed or verbal permission from land owners. Sampling permits were obtained from Northern Land Council (Northern Territory, Australia) prior to sample collection from Aboriginal communities. As per permit conditions, we obtained further permission from the community representatives prior to sampling. No specific permits were required for collection of the Thai isolates as they were obtained from unregulated public lands. Our field collection did not involve endangered or protected species.

Bacterial Isolates

Our laboratories have ongoing collections of isolates from soil and water samples obtained from both the Northern Territory and Thailand, comprising isolates that grow on ASA [13] yet are not B. pseudomallei according to the TTS1 assay [19]. These isolates were subjected to 16S sequencing, MLST, recA sequencing or whole-genome sequencing (WGS) as part of this and other studies to confirm genus and, where possible, for species assignment. All isolates were subcultured for purity on chocolate agar or ASA (Oxoid, Thetford, SA, Australia) prior to DNA extraction. The Qiagen DNeasy kit (Qiagen, Doncaster, VIC, Australia) was used for DNA extraction as previously described [20]. DNA was diluted 1:100 in molecular-grade H2O (prior to PCR.

Bioinformatic Analysis to Identify B. ubonensis-specific Loci

Nineteen B. pseudomallei near-neighbour isolates were subjected to WGS: Burkholderia spp. MSMB175, Burkholderia spp. MSMB49, B. cenocepacia MSMB101, B. cenocepacia MSMB139, Burkholderia multivorans MSMB104, B. multivorans MSMB105, Burkholderia oklahomensis C6786, B. pseudomallei MSHR684, B. pseudomallei MSHR1079, Burkholderia thailandensis-like strain MSMB121, B. thailandensis MSMB59, B. ubonensis MSMB56, B. pseudomallei MSMB106, B. ubonensis MSMB108, B. ubonensis MSMB145, B. ubonensis MSMB157, B. ubonensis MSMB166, B. ubonensis MSMB169 and B. ubonensis MSMB170. The Illumina GAIIx platform (Illumina, San Diego, CA, USA) was used to generate WGS data. An assembly of B. ubonensis MSMB170 was performed on paired-end Illumina v1.9 reads with Velvet v1.2.07 [21], using a kmer of 55. This assembly resulted in 836 contigs with an n50 of 5 kb. MSMB170 was subsequently used as a reference genome for read mapping with the Burrows-Wheeler Aligner (BWA) v0.5.9 [22]. The coverageBed module of BEDTools v2.15.0 [23] was used for presence/absence analysis based on a 1 kb window size. Candidate B. ubonensis-specific loci were identified by locating regions with 100% read coverage in all eight B. ubonensis strains but with <50% coverage in other Burkholderia species. Eleven candidate loci ≥5 kb were identified. One locus, Bu550, was chosen for real-time PCR assay design following confirmation of in silico specificity for B. ubonensis using Microbial Nucleotide BLAST.

B. ubonensis-specific Real-time PCR Assay Bu550

A fluorogenic probe-based real-time PCR assay (Bu550) was developed to target a candidate B. ubonensis-specific 7 kb locus. Four putative protein products are encoded within this locus; a major facilitator superfamily transporter (GenBank ID: WP_010089641), a hypothetical protein (WP_010089640), a carbamoyltransferase (WP_010089639) and a tannase
was performed in 384-well optical plates (Applied Biosystems, probes to ensure assay specificity and accuracy. Real-time PCR specificity. BLAST analysis was conducted on the primers and search Technologies, Novato, CA, USA) was included to increase characteristics to its potentially deadly near-neighbour, Burkholderia ubonensis.

Results

Phenotypic Diversity of B. Ubonensis Isolates on ASA

ASA is commonly used for isolation of B. pseudomallei from clinical and environmental isolates in endemic regions, and is commercially available in Australia. The isolates examined in our study contain a cross-section of isolates that grow on ASA but are TTS1-negative [19], and thus are not B. pseudomallei. Several species (e.g. Burkholderia diffusa, Chryseobacterium spp., Delftia spp., Ralstonia spp., Cupriavidus spp. and Acidovorax spp.) possessed morphologies (Figure 1) that were clearly distinguishable from the expected B. pseudomallei morphotypes [24]; in other cases, isolates were indistinguishable from B. pseudomallei. The latter category contained mostly Burkholderia spp., particularly B. absonensis, which demonstrated multiple morphotypes, many of which resembled B. pseudomallei morphotypes (Figure 1). This inability to differentiate most B. ubonensis strains from B. pseudomallei on ASA provided the impetus for the rest of this study.

Identification of a B. Ubonensis-specific Target from Whole-genome Sequence Data

Comparative whole-genome analysis of 19 Burkholderia spp., which included eight B. ubonensis strains, was performed using B. ubonensis MSMB170 as the reference genome. With this approach, we identified a candidate 7 kb locus specific for B. ubonensis, corresponding to a region within B. ubonensis Bu contig PMI006xBUxBu-101 (GenBank: ABBE01000101.1). Nucleotide BLAST analysis (http://blast.ncbi.nlm.nih.gov/) of 9,404 complete or draft microbial genomes confirmed specificity of this locus, with only a single significant hit occurring in B. ubonensis Bu (analysis performed 26-Mar-13).

PCR Assay Design and Screening of the B. Ubonensis-specific Assay

A Black Hole Quencher (BHQ) probe-based real-time PCR assay [25] was designed based on a conserved region within the 7 kb B. ubonensis-specific locus, encoding the hypothetical protein BuboB_03639. We chose BHQ probe technology due to its comparatively low cost compared with conventional TaqMan minor groove-binding probes (Applied Biosystems). In addition, the Bu550 assay can be multiplexed in a single PCR tube with the existing B. pseudomallei TTS1 BHQ assay [19] due to compatible CAL Fluor 540 and 6FAM fluorophore chemistries. The Bu550 assay was screened for specificity using a diverse panel of bacterial species that grow on ASA, with greatest representation of B. ubonensis and B. pseudomallei isolates (Table 1). In total, 306 isolates were tested, including 140 B. ubonensis and 86 B. pseudomallei isolates from Australia and Thailand. As predicted from in silico analyses, the Bu550 assay demonstrated 100% specificity for B. ubonensis, with all other examined species failing to amplify (Figure 2; Table 1). We obtained similar results with the TaqMan Environmental and Universal Master Mixes, although the

Figure 1. Colony morphologies of various B. pseudomallei near-neighbour species on Ashdown’s agar. Panels: A, Burkholderia ubonensis MSMB700; B, B. ubonensis MSMB704; C, B. ubonensis MSMB1138; D, B. ubonensis MSMB718; E, B. ubonensis MSMB1191; F, B. ubonensis MSMB1165; G, B. ubonensis MSMB1202; H, Pandoraea sp. MSMB824; I, Herbaspirillum seropedicae MSMB1000; J, Burkholderia diffusa MSMB1075; K, Chryseobacterium sp. MSMB1448; L, Cupriavidus metallidurans MSMB1495; M, Burkholderia vietnamiensis MSMB1224; N, Burkholderia multivorans MSMB1271; O, Burkholderia pyrogenia MSMB1147; P, Delftia sp. MSMB943; Q, Ralstonia mannitolilytica MSMB1253; R, Burkholderia thailandensis MSMB1415; S, Burkholderia cepacia MSMB1456; T, B. cepacia MSMB1011; U, Acidovorax caeni MSMB1260. On this medium, Burkholderia ubonensis demonstrates similar morphological characteristics to its potentially deadly near-neighbour, Burkholderia pseudomallei, including uptake of crystal violet and neutral red, and wrinkling of colonies after 72 h growth [13,24]. Molecular genotyping is therefore necessary for differentiation of B. ubonensis from other bacterial species that grow on Ashdown’s medium. Note the morphological differences among B. ubonensis strains; several morphotypes have also been observed in B. pseudomallei [24].
Environmental Master Mix provided more robust amplification (data not shown).

Discussion

Originally identified from soil collected in Ubont Ratchathani province, Thailand, in 1989 [16], *Burkholderia ubonensis* is now known to be an abundant environmental bacterium in northern Australia. Both regions are also endemic for *B. pseudomallei*, a pathogenic bacterium that causes significant morbidity and mortality, with up to 50% of infected individuals succumbing to disease [26]. Ashdown’s agar (ASA) is a common medium used in endemic regions to select *B. pseudomallei* from clinical and environmental specimens. However, ASA also supports the growth of other *Burkholderia* spp., several other Gram-negative bacteria and even some gentamicin-resistant strains of Gram-positive *Staphylococcus* spp. (Table 1; [27]). Of these non-*B. pseudomallei* species, we showed that *B. ubonensis* is the most frequently isolated in northern Australia due to its strong morphological resemblance to *B. pseudomallei*. Like *B. pseudomallei*, *B. ubonensis* possesses several morphotypes on ASA (Figure 1), many of which closely resemble *B. pseudomallei* morphotypes [24]. Therefore, it is impossible to differentiate *B. ubonensis* from *B. pseudomallei* based on morphological characteristics alone.

Due to the inherent difficulty in distinguishing *B. ubonensis* and *B. pseudomallei* based on morphology, we developed a cost-effective, rapid PCR-based method for differentiating *B. ubonensis* from other soil- and water-borne species that grow on ASA, particularly *B. pseudomallei*. Current methods of characterising *Burkholderia* spp. rely on dideoxy sequencing [8,17,18], which is an expensive and time-consuming endeavour for screening large isolate collections. We applied comparative whole-genome sequence analysis of 19 *Burkholderia* spp., including eight *B. ubonensis* isolates, to identify a locus specific for *B. ubonensis*. The specificity of one candidate locus, 550, was confirmed using in-depth *in silico* BLAST analysis. We subsequently developed a cost-effective real-time PCR assay, Bu550, for its interrogation. The performance of Bu550 was validated against a diverse collection of *Burkholderia*aeae and other bacterial species that grow on ASA, obtained from soil and water across the Northern Territory and Thailand. Our results indicate that Bu550 is highly specific towards *B. ubonensis*, with all other species we tested failing to amplify.

The design of the *B. ubonensis*-specific BHQ probe-based assay enables multiplex capability with the *B. pseudomallei*-specific assay, TTS1. *B. ubonensis* has demonstrated antagonistic activity towards *B. pseudomallei* and shows promise for biocontrol of naturally occurring *B. pseudomallei*, particularly in areas of high endemicity [15]. However, it is not yet known to what extent near-neighbour species such as *B. ubonensis* affect the natural prevalence of *B. pseudomallei*. Our future work will involve quantifying *B. ubonensis* and *B. pseudomallei* from soils obtained in *B. pseudomallei*-endemic regions to determine the relative abundance of these species, thereby improving our understanding of *B. pseudomallei* and *B. ubonensis* ecology. Bu550, in combination with TTS1, will be an important and valuable tool in such ecological studies.

Acknowledgments

We kindly thank Christopher Allender and Kevin Dreers (Northern Arizona University) and Yuwana Podin and Glenda Harrington (Menzies School of Health Research) for helpful discussions on *Burkholderia pseudomallei* near-neighbours and for assistance with laboratory aspects of this work. We also wish to thank colleagues at the Wellcome Trust-Mahidol University-Oxford Tropical Medicine Research Programme for assistance with soil sampling in Thailand that yielded some of the isolates utilized in this study.
